

On the Total Energy Efficiency of Cell-Free Massive MIMO

Hien Quoc Ngo, *Member, IEEE*, Le-Nam Tran, *Member, IEEE*, Trung Q. Duong, *Senior Member, IEEE*, Michail Matthaiou, *Senior Member, IEEE*, and Erik G. Larsson, *Fellow, IEEE*

Abstract

We consider the cell-free massive multiple-input multiple-output (MIMO) downlink, where a very large number of distributed multiple-antenna access points (APs) serve many single-antenna users in the same time-frequency resource. A simple (distributed) conjugate beamforming scheme is applied at each AP via the use of local channel state information (CSI). This CSI is acquired through time-division duplex operation and the reception of uplink training signals transmitted by the users. We derive a closed-form expression for the spectral efficiency taking into account the effects of channel estimation errors and power control. This closed-form result enables us to analyze the effects of backhaul power consumption, the number of APs, and the number of antennas per AP on the total energy efficiency, as well as, to design an optimal power allocation algorithm. The optimal power allocation algorithm aims at maximizing the total energy efficiency, subject to a per-user spectral efficiency constraint and a per-AP power constraint. Compared with the case of without power control, our proposed power allocation scheme can double the total energy efficiency. Furthermore, we propose AP selections schemes, in which each user chooses a subset of APs, to reduce the power consumption caused by the backhaul links. With our proposed AP selection schemes, the total energy efficiency increases significantly, especially for large numbers of APs. Moreover, under a requirement of good quality-of-service for all users, cell-free massive MIMO outperforms the colocated counterpart in terms of energy efficiency.

I. INTRODUCTION

The performance of cellular networks is typically limited by inter-cell interference. In particular, users close to the cell boundaries suffer from strong interference (relative to their desired signal powers). Network multiple-input multiple-output (MIMO) (also referred to as distributed MIMO, coordinated multi-point transmission, and distributed antenna systems) can reduce such inter-cell interference through coherent cooperation between base stations [1]. In network MIMO, base stations cooperate via advanced backhaul links to jointly transmit signals in the downlink and jointly detect signals in the uplink. However, it was shown in [2] that base station cooperation has fundamental limitations, i.e., even with full cooperation between the base stations, the spectral efficiency is upper-bounded by a finite constant when the transmit power goes to infinity. However, this does not mean that cooperation has no benefits. Cooperation can still yield significant higher spectral efficiencies and coverage probabilities compared to the case where interference is ignored [2]. Consequently, there has been a great deal of interest in network MIMO over the past decade [3]–[5]. The main challenges in the implementation of network MIMO are the need for a substantial backhaul overhead, high deployment costs, and a sufficiently capable central processing unit. In particular, precoded signals and channel state information (CSI) need to be shared among the base stations.

Recently, cell-free massive MIMO has been introduced as a practical and useful embodiment of the network MIMO concept [6]. In cell-free massive MIMO, a large number of access points (APs) equipped with single or multiple antennas, and distributed over a large area, coherently serve a large number of users in the same time-frequency resource. As in (cellular) colocated massive MIMO [7], cell-free massive MIMO exploits the favorable propagation and channel hardening properties when the number of APs is large to multiplex many users in the same time-frequency resource with small inter-user interference. Thus, it can offer a huge spectral efficiency with simple signal processing. More importantly, in a cell-free massive MIMO configuration, the service antennas are brought close to the users, which yields a high degree of macro-diversity and low path losses [6]; hence, many users can be served simultaneously with uniformly good quality-of-service. Furthermore, it was shown in [6] that cell-free massive MIMO has significantly better performance than conventional small-cell systems, where each user is served by a single AP. For these reasons, cell-free massive MIMO is as a promising technology for next generation

wireless systems.

Despite its potential, however, besides [6] there is fairly little work on cell-free massive MIMO available in the literature. In [8], the performance of cell-free massive MIMO with zero-forcing processing was analyzed, under the assumption that all pilot sequences assigned to the users were mutually orthogonal. Cell-free massive MIMO with beamformed downlink training was investigated in [9]. The conclusion was that by beamforming the pilots, the performance of the cell-free massive MIMO downlink can be substantially improved. A compute-and-forward approach for cell-free massive MIMO to reduce the backhaul load was proposed and analyzed in [10]. All the above-cited works assumed that the APs have only a single antenna. However, the APs can be equipped with multiple antennas to increase the diversity and array gains, as well as, reduce the backhaul requirements. In addition, while it is well-known that colocated massive MIMO is energy-efficient [11], it is not yet clear how good the energy efficiency of cell-free massive MIMO is. The argument is that in cell-free massive MIMO, more backhaul links are required which potentially increase the total power consumption to such a level that can overwhelm the achieved spectral efficiency.

Motivated by the above discussion, in this work we consider a cell-free massive MIMO system with multiple antennas at each AP and time-division duplex (TDD) operation. All APs cooperate via a backhaul network to jointly transmit signals to all users in the same time-frequency resource. The transmission is performed through the use of conjugate beamforming. The total energy efficiency of this system is investigated. The specific contributions of the paper are as follows:

- We derive a closed-form expression for the spectral efficiency of the downlink channel with any finite numbers of APs and users and arbitrary pilot sequences assigned to the users. Our result is a generalization of the results for colocated massive MIMO in [7] and cell-free massive MIMO with single-antenna APs in [6].
- We investigate the total energy efficiency of our considered system taking into account the hardware power consumption and the power consumption of the backhaul. We propose an optimal power control algorithm which aims at maximizing the total energy efficiency, under a per-user spectral efficiency constraint and a per-AP power constraint. The solution to this power control problem can be approximately determined by solving a sequence of second-order cone programs (SOCPs) [12].

- We study the effect of the backhaul power consumption, and show that the backhaul power consumption significantly affects the energy efficiency, especially when the number of APs is large. To reduce this effect, we propose two AP selection schemes: received-power-based selection and largest-large-scale-fading-based selection. Then, the performances of cell-free massive MIMO and colocated massive MIMO are quantitatively compared.

The remainder of paper is organized as follows. In Section II, we describe the cell-free massive MIMO system model and derive the downlink spectral efficiency. In Section III, we present the power consumption model and the corresponding energy efficiency. The power control and access point selection schemes are discussed in Sections IV and V, respectively. Numerical results and discussions are provided in Section VI, while Section VII concludes the paper.

Notation: Boldface lower case and upper case letters are used for column vectors and matrices, respectively. The superscripts $()^*$, $()^T$, and $()^H$ stand for the conjugate, transpose, and conjugate-transpose, respectively. The Euclidean norm and the expectation operators are denoted by $\|\cdot\|$ and $\mathbb{E}\{\cdot\}$, respectively. Furthermore, $[\mathbf{x}]_n$ is the n th element of vector $\mathbf{x}$. Finally, $z \sim \mathcal{CN}(0, \sigma^2)$ denotes a circularly symmetric complex Gaussian random variable (RV) z with zero mean and variance σ^2 , and $z \sim \mathcal{N}(0, \sigma^2)$ denotes a real-valued Gaussian RV.

II. SYSTEM MODEL AND SPECTRAL EFFICIENCY

A. System Model

We consider a cell-free massive MIMO system where M APs serve K users in the same time-frequency resource under TDD operation. Each AP is equipped with N antennas, while each user has a single antenna. We assume that the APs and the users are randomly located in a large area. We further assume that $M \gg K$. For TDD operation in the context of massive MIMO, existing literature typically considers three phases within each coherence interval: uplink training, uplink payload data transmission, and downlink payload data transmission. In this work, we focus on the downlink, and thus the uplink payload data transmission phase is neglected. The system model is similar to that in [6], but an important distinction is that the APs have multiple antennas herein. Let τ_c be the length of each coherence interval (in samples). A part of the coherence interval is used for uplink training. The length of this duration is denoted by τ_p , $\tau_p < \tau_c$. The remaining duration, $(\tau_c - \tau_p)$, is used for the downlink payload data transmission.

1) *Uplink Training*: In the uplink training phase, all K users simultaneously transmit their pilot sequences to all APs. From the received pilot signals, the APs can then estimate the channels. Let $\sqrt{\tau_p}\boldsymbol{\varphi}_k \in \mathbb{C}^{\tau_p \times 1}$, where $\|\boldsymbol{\varphi}_k\|^2 = 1$, be the pilot sequence transmitted from the k th user, $k = 1, \dots, K$. Then, the m th AP receives

$$\mathbf{Y}_{p,m} = \sqrt{\tau_p \rho_p} \sum_{k=1}^K \mathbf{g}_{mk} \boldsymbol{\varphi}_k^H + \mathbf{W}_{p,m}, \quad (1)$$

where ρ_p is the normalized transmit signal-to-noise ratio (SNR) of each pilot symbol, $\mathbf{W}_{p,m}$ is an $N \times \tau_p$ noise matrix whose elements are independent and identically distributed (i.i.d.) $\mathcal{CN}(0, 1)$ RVs, and $\mathbf{g}_{mk} \in \mathbb{C}^{N \times 1}$ is the channel vector between the m th AP and the k th user. The channel $\mathbf{g}_{mk} \in \mathbb{C}^{N \times 1}$ models the propagation as follows:

$$\mathbf{g}_{mk} = \beta_{mk}^{1/2} \mathbf{h}_{mk}, \quad (2)$$

where β_{mk} represents the large-scale fading which does not depend on the antenna indexes at the AP, and $\mathbf{h}_{mk}$ is an $N \times 1$ vector of small-scale fading coefficients between the N antennas of the m th AP and the k th user. We assume that small-scale fading is Rayleigh fading, i.e., the elements of $\mathbf{h}_{mk}$ are i.i.d. $\mathcal{CN}(0, 1)$ RVs.

To estimate the channels $\mathbf{g}_{mk}$, $k = 1, \dots, K$, the m th AP first performs a de-spreading operation by multiplying the received signal by the pilot sequence $\boldsymbol{\varphi}_k$,

$$\begin{aligned} \check{\mathbf{y}}_{p,mk} &\triangleq \mathbf{Y}_{p,m} \boldsymbol{\varphi}_k \\ &= \sqrt{\tau_p \rho_p} \mathbf{g}_{mk} + \sqrt{\tau_p \rho_p} \sum_{k' \neq k}^K \mathbf{g}_{mk'} \boldsymbol{\varphi}_{k'}^H \boldsymbol{\varphi}_k + \tilde{\mathbf{w}}_{p,mk}, \end{aligned} \quad (3)$$

where $\tilde{\mathbf{w}}_{p,mk} \triangleq \mathbf{W}_{p,m} \boldsymbol{\varphi}_k$. Since $\|\boldsymbol{\varphi}_k\|^2 = 1$, $\tilde{\mathbf{w}}_{p,mk}$ has i.i.d. $\mathcal{CN}(0, 1)$ components. Then, the m th AP is assumed to adopt the minimum mean-square error (MMSE) method to estimate the channel as

$$\begin{aligned} \hat{\mathbf{g}}_{mk} &= \mathbb{E} \{ \mathbf{g}_{mk} \check{\mathbf{y}}_{p,mk}^H \} \left(\mathbb{E} \{ \check{\mathbf{y}}_{p,mk} \check{\mathbf{y}}_{p,mk}^H \} \right)^{-1} \check{\mathbf{y}}_{p,mk} \\ &= \frac{\sqrt{\tau_p \rho_p} \beta_{mk}}{\tau_p \rho_p \sum_{k'=1}^K \beta_{mk'} |\boldsymbol{\varphi}_{k'}^H \boldsymbol{\varphi}_k|^2 + 1} \check{\mathbf{y}}_{p,mk}. \end{aligned} \quad (4)$$

The channel estimate $\hat{\mathbf{g}}_{mk}$ includes N independent and identical Gaussian components. The mean-square of the n th component is denoted by γ_{mk} , and given by

$$\begin{aligned}\gamma_{mk} &\triangleq \mathbb{E} \{ |[\hat{\mathbf{g}}_{mk}]_n|^2 \} \\ &= \frac{\tau_p \rho_p \beta_{mk}^2}{\tau_p \rho_p \sum_{k'=1}^K \beta_{mk'} |\boldsymbol{\varphi}_{k'}^H \boldsymbol{\varphi}_k|^2 + 1}.\end{aligned}\quad (5)$$

Denote by $\tilde{\mathbf{g}}_{mk} = \mathbf{g}_{mk} - \hat{\mathbf{g}}_{mk}$ the channel estimation error. From the MMSE estimation property, $\tilde{\mathbf{g}}_{mk}$ is independent of $\hat{\mathbf{g}}_{mk}$. The elements of $\tilde{\mathbf{g}}_{mk}$ are i.i.d. $\mathcal{CN}(0, \beta_{mk} - \gamma_{mk})$ RVs.

2) *Downlink Payload Data Transmission:* After acquiring the channels from the uplink pilots, the APs use conjugate beamforming to transmit signals to the K users. Our choice of conjugate beamforming is inspired by the fact that it is computationally simple with most processing done locally at the APs, and it offers excellent performance [6]. Denote the symbol intended for the k th user by q_k , where $\mathbb{E} \{ |q_k|^2 \} = 1$, $k = 1, \dots, K$. The vector of transmitted signals from the m th AP, $\mathbf{x}_m$, is generated by first scaling the K symbols with the power control coefficients $\{\eta_{mk}\}$, and then multiplying them with the conjugate of the channel estimates as follows:

$$\mathbf{x}_m = \sqrt{\rho_d} \sum_{k=1}^K \sqrt{\eta_{mk}} \hat{\mathbf{g}}_{mk}^* q_k, \quad (6)$$

where ρ_d is the maximum normalized transmit power (normalized by the noise power N_0) at each AP. The normalized transmitted power is

$$\mathbb{E} \{ \|\mathbf{x}_m\|^2 \} = \rho_d N \sum_{k=1}^K \eta_{mk} \gamma_{mk}. \quad (7)$$

The power control coefficients $\{\eta_{mk}\}$ are chosen to satisfy the power constraint at each AP, $\mathbb{E} \{ \|\mathbf{x}_m\|^2 \} \leq \rho_d$. Thus,

$$\sum_{k=1}^K \eta_{mk} \gamma_{mk} \leq \frac{1}{N}, \quad \text{for all } m = 1, \dots, M. \quad (8)$$

With the transmitted signal vector $\mathbf{x}_m$ given in (6), the k th user receives

$$\begin{aligned}r_k &= \sum_{m=1}^M \mathbf{g}_{mk}^T \mathbf{x}_m + w_k \\ &= \sqrt{\rho_d} \sum_{m=1}^M \sqrt{\eta_{mk}} \mathbf{g}_{mk}^T \hat{\mathbf{g}}_{mk}^* q_k + \sqrt{\rho_d} \sum_{k' \neq k}^K \sum_{m=1}^M \sqrt{\eta_{mk'}} \mathbf{g}_{mk}^T \hat{\mathbf{g}}_{mk'}^* q_{k'} + w_k,\end{aligned}\quad (9)$$

where $w_k \sim \mathcal{CN}(0, 1)$ is the additive noise.

B. Spectral Efficiency

The k th user will detect its desired signal q_k from the received signal r_k given by (9). To do so, the k th user needs to know the effective channel gain $\sum_{m=1}^M \sqrt{\eta_{mk}} \mathbf{g}_{mk}^T \hat{\mathbf{g}}_{mk}^*$. Since there are no downlink pilots, the k th user uses its knowledge of the channel statistics to detect q_k . More precisely, the k th user treats the mean of the effective channel gain as the true channel for signal detection. This technique has been widely used in the massive MIMO context [7]. With this technique, the received signal r_k given in (9) can be rewritten as

$$r_k = \underbrace{\sqrt{\rho_d} \mathbb{E} \left\{ \sum_{m=1}^M \sqrt{\eta_{mk}} \mathbf{g}_{mk}^T \hat{\mathbf{g}}_{mk}^* \right\}}_{\text{desired signal}} q_k + \underbrace{\sqrt{\rho_d} \left(\sum_{m=1}^M \sqrt{\eta_{mk}} \mathbf{g}_{mk}^T \hat{\mathbf{g}}_{mk}^* - \mathbb{E} \left\{ \sum_{m=1}^M \sqrt{\eta_{mk}} \mathbf{g}_{mk}^T \hat{\mathbf{g}}_{mk}^* \right\} \right)}_{\text{effective noise}} q_k + \sqrt{\rho_d} \sum_{k' \neq k}^K \sum_{m=1}^M \sqrt{\eta_{mk'}} \mathbf{g}_{mk'}^T \hat{\mathbf{g}}_{mk'}^* q_{k'} + w_k. \quad (10)$$

By using the capacity bound in [7, Section 2.3], the corresponding spectral efficiency (expressed in bit/s/Hz) of the k th user is given by

$$S_{ek} = \left(1 - \frac{\tau_p}{\tau_c} \right) \log_2 \left(1 + \frac{|\text{DS}_k|^2}{\mathbb{E} \{ |\text{BU}_k|^2 \} + \sum_{k' \neq k}^K \mathbb{E} \{ |\text{UI}_{kk'}|^2 \} + 1} \right), \quad (11)$$

where DS_k , BU_k , and $\text{UI}_{kk'}$ represent the desired signal, the beamforming uncertainty gain, and the inter-user interference, respectively, given by

$$\text{DS}_k \triangleq \sqrt{\rho_d} \mathbb{E} \left\{ \sum_{m=1}^M \sqrt{\eta_{mk}} \mathbf{g}_{mk}^T \hat{\mathbf{g}}_{mk}^* \right\}, \quad (12)$$

$$\text{BU}_k \triangleq \sqrt{\rho_d} \left(\sum_{m=1}^M \sqrt{\eta_{mk}} \mathbf{g}_{mk}^T \hat{\mathbf{g}}_{mk}^* - \mathbb{E} \left\{ \sum_{m=1}^M \sqrt{\eta_{mk}} \mathbf{g}_{mk}^T \hat{\mathbf{g}}_{mk}^* \right\} \right), \quad (13)$$

$$\text{UI}_{kk'} \triangleq \sqrt{\rho_d} \sum_{m=1}^M \sqrt{\eta_{mk'}} \mathbf{g}_{mk'}^T \hat{\mathbf{g}}_{mk'}^*. \quad (14)$$

In the following, we present an exact closed-form expression for the spectral efficiency (11).

Proposition 1: The spectral efficiency of the transmission from the APs to the k th user given in (11) can be represented in closed-form as

$$S_{ek}(\{\eta_{mk}\}) = \left(1 - \frac{\tau_p}{\tau_c} \right) \log_2 \left(1 + \frac{\rho_d N^2 |\bar{\gamma}_{kk}^T \bar{\eta}_k|^2}{\rho_d N^2 \sum_{k' \neq k}^K |\bar{\gamma}_{k'k}^T \bar{\eta}_{k'}|^2 + \rho_d N \sum_{k'=1}^K \|\mathbf{D}_{k'k} \bar{\eta}_{k'}\|_2^2 + 1} \right), \quad (15)$$

where $\bar{\boldsymbol{\eta}}_k \triangleq [\sqrt{\eta_{1k}}, \dots, \sqrt{\eta_{Mk}}]^T \in \mathbb{R}_+^M$, consists of all power control coefficients associated with user k , $\mathbf{D}_{k'k}$ is a $\mathbb{R}^{M \times M}$ diagonal matrix whose m th diagonal entry is given by $[\mathbf{D}_{k'k}]_{m,m} = \sqrt{\gamma_{mk'}\beta_{mk}}$, and

$$\bar{\boldsymbol{\gamma}}_{k'k} \triangleq |\boldsymbol{\varphi}_{k'}^H \boldsymbol{\varphi}_k| \left[\gamma_{1k'} \frac{\beta_{1k}}{\beta_{1k'}}, \gamma_{2k'} \frac{\beta_{2k}}{\beta_{2k'}}, \dots, \gamma_{Mk'} \frac{\beta_{Mk}}{\beta_{Mk'}} \right]^T.$$

Proof: See Appendix A. □

Note that in the special case that all APs are equipped with a single antenna ($N = 1$), the spectral efficiency (15) is identical to the spectral efficiency in [6, Eq. (24)]. If we replace N with M and M with 1, we have the spectral efficiency for the colocated massive MIMO system in [7, Table 3.2]. The sum spectral efficiency is given by

$$S_e(\{\eta_{mk}\}) = \sum_{k=1}^K S_{ek}(\{\eta_{mk}\}). \quad (16)$$

III. POWER CONSUMPTION MODEL AND ENERGY EFFICIENCY

A. Power Consumption Model

We consider a power consumption model widely used in the literature [11], [13]–[15]. With this model, the total power consumption is the sum of a fixed power part, the transmit power, the circuit power consumption, and the power consumption of the backhaul. More precisely, the total power consumption is modeled as

$$P_{\text{total}} = \sum_{m=1}^M P_m + \sum_{m=1}^M P_{\text{bh},m}, \quad (17)$$

where P_m is the power consumption at the m th AP due to the amplifier and the circuit power consumption part (including the power consumption of the transceiver chains and the power consumed for signal processing), and $P_{\text{bh},m}$ is the power consumed by the backhaul link connecting the central processing unit (CPU) and the m th AP. The power consumption P_m can be modeled as

$$P_m = \frac{1}{\alpha_m} \rho_d N_0 \left(N \sum_{k=1}^K \eta_{mk} \gamma_{mk} \right) + N P_{\text{tc},m}, \quad (18)$$

where $0 < \alpha_m \leq 1$ is the power amplifier efficiency, N_0 is the noise power, and $P_{\text{tc},m}$ is the internal power required to run the circuit components (e.g. converters, mixers, and filters) related to each antenna of the m th AP.

The backhaul is used to transfer the data between the APs and the CPU, and its power consumption is proportional to the sum spectral efficiency,

$$P_{\text{bh},m} = P_{0,m} + B \cdot S_e \cdot P_{\text{bt},m}, \quad (19)$$

where $P_{0,m}$ is a fixed power consumption of each backhaul (traffic-independent power) which may depend on the distances between the APs and the CPU and the system topology, $P_{\text{bt},m}$ is the traffic-dependent power (in Watt per bit/s), and B is the system bandwidth.¹

The substitution of (18) and (19) into (17) yields

$$P_{\text{total}} = \rho_d N_0 \sum_{m=1}^M \frac{1}{\alpha_m} \left(N \sum_{k=1}^K \eta_{mk} \gamma_{mk} \right) + \sum_{m=1}^M (N P_{\text{tc},m} + P_{0,m}) + B \left(\sum_{m=1}^M P_{\text{bt},m} \right) S_e. \quad (20)$$

B. Total Energy Efficiency

The total energy efficiency (bit/Joule) is defined as the sum throughput (bit/s) divided by the total power consumption (Watt) in the network:

$$E_e = \frac{B \cdot S_e}{P_{\text{total}}}, \quad (21)$$

where B is again the system bandwidth.

IV. TOTAL ENERGY EFFICIENCY MAXIMIZATION

We aim at allocating the power coefficients $\{\eta_{mk}\}$ to maximize the total energy efficiency, under the constraints on per-user spectral efficiency and transmit power at each AP. More precisely, the optimization problem is formulated as follows:

$$(\mathcal{P}) : \begin{cases} \max_{\{\eta_{mk}\}} E_e(\{\eta_{mk}\}) \\ \text{s.t.} & S_{ek}(\{\eta_{mk}\}) \geq S_{ok}, \quad k = 1, \dots, K \\ & \sum_{k=1}^K \eta_{mk} \gamma_{mk} \leq 1/N, \quad m = 1, \dots, M \\ & \eta_{mk} \geq 0, \quad k = 1, \dots, K, \quad m = 1, \dots, M, \end{cases} \quad (22)$$

¹The backhaul is also used to transfer the power allocation coefficients, synchronization signals, etc. This is done once per large-scale fading realization which stays constant for many coherence intervals. Therefore, we neglect the power consumed by this processing.

where S_{ok} is the minimum spectral efficiency required by the k th user. From (20) and (21), the optimization problem (22) can be rewritten as

$$(\mathcal{P}) : \begin{cases} \max_{\{\eta_{mk}\}} & \frac{B \cdot S_e(\{\eta_{mk}\})}{\bar{P}_{\text{fix}} + \rho_d N_0 N \sum_{m=1}^M \frac{1}{\alpha_m} \sum_{k=1}^K \eta_{mk} \gamma_{mk} + B \left(\sum_{m=1}^M P_{\text{bt},m} \right) S_e(\{\eta_{mk}\})} \\ \text{s.t.} & S_{ek}(\{\eta_{mk}\}) \geq S_{ok}, \quad k = 1, \dots, K \\ & \sum_{k=1}^K \eta_{mk} \gamma_{mk} \leq 1/N, \quad m = 1, \dots, M \\ & \eta_{mk} \geq 0, \quad k = 1, \dots, K, \quad M = 1, \dots, M, \end{cases} \quad (23)$$

where $\bar{P}_{\text{fix}} \triangleq \sum_{m=1}^M (NP_{\text{ic},m} + P_{0,m})$ is independent of $\{\eta_{mk}\}$.

By dividing the numerator and the denominator of the objective function of $(\mathcal{P})$ by $B \cdot S_e(\{\eta_{mk}\})$, we can see that the objective function increases as

$$\frac{B \cdot S_e(\{\eta_{mk}\})}{\bar{P}_{\text{fix}} + \rho_d N_0 N \sum_{m=1}^M \frac{1}{\alpha_m} \sum_{k=1}^K \eta_{mk} \gamma_{mk}}.$$

Therefore, the optimization problem $(\mathcal{P})$ is equivalent to

$$(\mathcal{P}_1) : \begin{cases} \max_{\{\eta_{mk}\}} & \frac{B \cdot S_e(\{\eta_{mk}\})}{\bar{P}_{\text{fix}} + \rho_d N_0 N \sum_{m=1}^M \frac{1}{\alpha_m} \sum_{k=1}^K \eta_{mk} \gamma_{mk}} & (24a) \\ \text{s.t.} & S_{ek}(\{\eta_{mk}\}) \geq S_{ok}, \quad k = 1, \dots, K, & (24b) \\ & \sum_{k=1}^K \eta_{mk} \gamma_{mk} \leq 1/N, \quad m = 1, \dots, M, & (24c) \\ & \eta_{mk} \geq 0, \quad k = 1, \dots, K, \quad M = 1, \dots, M. & (24d) \end{cases}$$

We note that the problem $(\mathcal{P}_1)$ is nonconvex and sequential convex approximation (SCA) will be applied to find a high-performance solution. To arrive at a more tractable formulation, we now show that (24b) indeed admits an equivalent convex expression. Towards this end, denote by $c_{mk} \triangleq \sqrt{\eta_{mk}}$, $\mathbf{c}_k \triangleq [c_{1k}, \dots, c_{Mk}]^T$, and $\mathbf{c} \triangleq [\mathbf{c}_1^T, \dots, \mathbf{c}_K^T]^T$. Then the optimization problem

$(\mathcal{P}_1)$ can be rewritten as

$$(\mathcal{P}_1) : \begin{cases} \max_{\mathbf{c}} & \frac{B \cdot \mathbf{S}_e(\mathbf{c})}{\bar{P}_{\text{fix}} + \rho_d N_0 N \sum_{m=1}^M \frac{1}{\alpha_m} \sum_{k=1}^K c_{mk}^2 \gamma_{mk}} & (25a) \\ \text{s.t.} & \mathbf{S}_{ek}(\mathbf{c}) \geq \mathbf{S}_{ok}, \quad k = 1, \dots, K, & (25b) \\ & \sum_{k=1}^K c_{mk}^2 \gamma_{mk} \leq 1/N, \quad m = 1, \dots, M, & (25c) \\ & c_{mk} \geq 0, \quad k = 1, \dots, K, \quad M = 1, \dots, M, & (25d) \end{cases}$$

where

$$\mathbf{S}_{ek}(\mathbf{c}) \triangleq \left(1 - \frac{\tau_p}{\tau_c}\right) \log_2 \left(1 + \frac{\rho_d N^2 |\bar{\gamma}_{kk}^T \mathbf{c}_k|^2}{\rho_d N^2 \sum_{k' \neq k}^K |\bar{\gamma}_{k'k}^T \mathbf{c}_{k'}|^2 + \rho_d N \sum_{k'=1}^K \|\mathbf{D}_{k'k} \mathbf{c}_{k'}\|_2^2 + 1}\right). \quad (26)$$

It is now clear that (25b) is equivalent to the following second order cone (SOC) constraint

$$\bar{\gamma}_{kk}^T \mathbf{c}_k \geq \sqrt{(2\bar{\mathbf{S}}_{ok} - 1) \left(\sum_{k' \neq k}^K |\bar{\gamma}_{k'k}^T \mathbf{c}_{k'}|^2 + \frac{1}{N} \sum_{k'=1}^K \|\mathbf{D}_{k'k} \mathbf{c}_{k'}\|_2^2 + \frac{1}{N^2 \rho_d} \right)}, \quad (27)$$

where $\bar{\mathbf{S}}_{ok} \triangleq \frac{\tau_c}{\tau_c - \tau_p} \mathbf{S}_{ok}$.

Next we further rewrite $(\mathcal{P}_1)$ as the following optimization problem

$$(\hat{\mathcal{P}}_1) : \begin{cases} \max_{\mathbf{c}, \mathbf{t}, t_0} & B \frac{\sum_{k=1}^K t_k}{t_0} & (28a) \\ \text{s.t.} & \mathbf{S}_{ek}(\mathbf{c}) \geq t_k, \quad k = 1, \dots, K & (28b) \\ & \bar{P}_{\text{fix}} + \rho_d N_0 N \sum_{m=1}^M \frac{1}{\alpha_m} \sum_{k=1}^K c_{mk}^2 \gamma_{mk} \leq t_0 & (28c) \\ & (25c), (25d), (27), & (28d) \end{cases}$$

where $\mathbf{t} \triangleq [t_1, \dots, t_K]^T$. It is easy to see that if $(c_{mk}, \mathbf{t}, t_0)$ solves $(\hat{\mathcal{P}}_1)$, then $c_{m,k}$ solves $(\mathcal{P}_1)$.

The proof is due to the fact that at optimality, all the constraints (28b) and (28c) hold with equality. Our motivation for the above maneuver is twofold. First, the objective in (28) is a linear fractional function which is much easier to handle, from a viewpoint of Charnes-Cooper transformation that we shall show shortly. Second, the reformulation given in (28) facilitates a customization of the branch-and-bound method based on monotonic optimization to find an optimal solution, which is described next.

Specifically, the formulation of $(\hat{\mathcal{P}}_1)$ reveals three important observations: (i) the objective in (28a) is monotonically increasing with $\mathbf{t}$ and $1/t_0$; (ii) for a given fixed $\mathbf{t}$ and $1/t_0$, the constraints in (28b) and (28c) are convex; and (iii) the constraints (25c), (25d), (27) are convex. These three facts simply mean that a globally optimal solution can be found using a monotonic optimization method, i.e., the branch-and-reduce-and bound (BRB) method [16]. However, such a global optimization method generally induces very high computational complexity, especially for our cell-free massive MIMO system where the number of APs and the number of users are very large. Therefore, we propose a sub-optimal solution which has low computational complexity and is shown to achieve a performance close to the optimal one. The method is based on the SCA method [17]–[19].

It is obvious that the troublesome constraint in (28) is (28b), which is non-convex. To deal with this nonconvex constraint, we introduce slack variables u_k , $k = 1, \dots, K$, and rewrite it as

$$1 + \frac{\rho_d N^2 |\bar{\gamma}_{kk}^T \mathbf{c}_k|^2}{\rho_d N^2 \sum_{k' \neq k} |\bar{\gamma}_{k'k}^T \mathbf{c}_{k'}|^2 + \rho_d N \sum_{k'=1}^K \|\mathbf{D}_{k'k} \mathbf{c}_{k'}\|_2^2 + 1} \geq u_k, \quad (29a)$$

$$\log_2(u_k) \geq \frac{\tau_c}{\tau_c - \tau_p} t_k. \quad (29b)$$

The constraint in (29a) is equivalent to

$$f(\mathbf{c}, u_k) \geq \rho_d N^2 \sum_{k' \neq k} |\bar{\gamma}_{k'k}^T \mathbf{c}_{k'}|^2 + \rho_d N \sum_{k'=1}^K \|\mathbf{D}_{k'k} \mathbf{c}_{k'}\|_2^2 + 1, \quad (30)$$

where

$$f(\mathbf{c}, u_k) \triangleq \frac{\rho_d N^2 \sum_{k'=1}^K |\bar{\gamma}_{k'k}^T \mathbf{c}_{k'}|^2 + \rho_d N \sum_{k'=1}^K \|\mathbf{D}_{k'k} \mathbf{c}_{k'}\|_2^2 + 1}{u_k}. \quad (31)$$

Note that $f(\mathbf{c}, u_k)$ defined in (31) is a quadratic-over-linear function which is jointly convex in $\mathbf{c}$ and u_k . In light of SCA, we can approximate it by a first-order Taylor expansion of (31). Specifically, let $\mathbf{c}^n$ and u_k^n be the values of $\mathbf{c}$ and u_k after n iterations of the SCA process. Then, we can replace (30) with

$$F(\mathbf{c}, u_k; \mathbf{c}^n, u_k^n) \geq \rho_d N^2 \sum_{k' \neq k} |\bar{\gamma}_{k'k}^T \mathbf{c}_{k'}^n|^2 + \rho_d N \sum_{k'=1}^K \|\mathbf{D}_{k'k} \mathbf{c}_{k'}^n\|_2^2 + 1, \quad (32)$$

where

$$\begin{aligned}
F(\mathbf{c}, u_k; \mathbf{c}^n, u_k^n) &= f(\mathbf{c}^n, u_k^n) + \nabla_{\mathbf{c}} f(\mathbf{c}^n, u_k^n)^T (\mathbf{c} - \mathbf{c}^n) + \partial_{u_k} f(\mathbf{c}^n, u_k^n) (u_k - u_k^n) \\
&= f(\mathbf{c}^n, u_k^n) + \frac{2\rho_d}{u_k^n} \sum_{k'=1}^K \mathbf{c}_{k'}^{nT} (N^2 \bar{\boldsymbol{\gamma}}_{k'k} \bar{\boldsymbol{\gamma}}_{k'k}^T + N \mathbf{D}_{k'k}^2) (\mathbf{c}_{k'} - \mathbf{c}_{k'}^n) \\
&\quad - \frac{f(\mathbf{c}^n, u_k^n)}{u_k^n} (u_k - u_k^n),
\end{aligned} \tag{33}$$

where in the last equality we have used the identity

$$\nabla_{\mathbf{x}} (\mathbf{x}^T \mathbf{A} \mathbf{x}) = (\mathbf{A} + \mathbf{A}^T) \mathbf{x}.$$

Note that (32) is SOC representable [20].

The constraint in (29b) deserves special attention. In fact it is a convex constraint and thus convex approximation is not necessary as convexity should be preserved. In this way, however, the resulting convex program cannot be cast into a more standard form for which powerful solvers are available. More specifically, if (29b) is kept as it is, then we obtain a convex problem that is a mix of second order and exponential cones. Solvers for such a convex problem do exist [21], but our numerical experiments reveal that they are not scalable with the problem size. To arrive at a more computationally efficient formulation, our idea is to approximate (29b) by a more tractable constraint, i.e., an SOC one. Accordingly to the SCA principle, we need to find a convex lower bound of the right hand side of (29b). To this end we recall the following inequality

$$\ln(x) \geq 1 - \frac{1}{x},$$

which leads to

$$\log_2(u_k) \geq \log_2(u_k^n) + \log_2(e) \left(1 - \frac{u_k^n}{u_k}\right). \tag{34}$$

Note that the above inequality holds with equality when $u_k = u_k^n$. Moreover, the first derivative of both sides of (34) is the same when $u_k = u_k^n$. That is, the right hand side of (34) is a proper convex bound in light of SCA [17], [18]. Therefore, the constraint (29b) can be replaced by

$$\log_2(u_k^n) + \log_2(e) \left(1 - \frac{u_k^n}{u_k}\right) \geq \frac{\tau_c}{\tau_c - \tau_p} t_k. \tag{35}$$

We remark that the above constraint can be reformulated as an SOC constraint [12]. In summary, the problem at the $(n + 1)$ th iteration of the proposed method is given by

$$(\hat{\mathcal{P}}_{1,n+1}) : \begin{cases} \max_{c_{m,k}, \dot{\mathbf{t}}, \mathbf{u}} & B \frac{\sum_{k=1}^K t_k}{t_0} \\ \text{s.t.} & (25\text{c}), (25\text{d}), (27), (28\text{c}), (32), (35). \end{cases} \quad (36\text{a})$$

By using a perspective transformation, $(\hat{\mathcal{P}}_{1,n+1})$ can be reformulated as an SOCP as

$$(\hat{\mathcal{P}}_{1,n+1}) : \begin{cases} \max_{\dot{c}_{m,k}, \dot{\mathbf{t}}, \dot{\mathbf{u}}, \theta} & B \sum_{k=1}^K \dot{t}_k \\ \text{s.t.} & \sum_{k=1}^K \dot{c}_{mk}^2 \gamma_{mk} \leq \theta^2 / N, \quad m = 1, \dots, M \\ & \dot{c}_{mk} \geq 0, \quad k = 1, \dots, K, \quad M = 1, \dots, M, \\ & |\bar{\boldsymbol{\gamma}}_{kk}^T \dot{\mathbf{c}}_k| \geq \sqrt{(2\bar{\mathbf{S}}_{ok} - 1) \left(\sum_{k' \neq k}^K |\bar{\boldsymbol{\gamma}}_{k'k}^T \dot{\mathbf{c}}_{k'}|^2 + \frac{1}{N} \sum_{k'=1}^K \|\mathbf{D}_{k'k} \dot{\mathbf{c}}_{k'}\|_2^2 + \frac{\theta^2}{N^2 \rho_d} \right)} \\ & \bar{P}_{\text{fix}} \theta^2 + \rho_d N_0 N \sum_{m=1}^M \frac{1}{\alpha_m} \sum_{k=1}^K \dot{c}_{mk}^2 \gamma_{mk} \leq \theta \\ & \theta (\log_2(u_k^n) + \log_2(e)) \geq \frac{\tau_c}{\tau_c - \tau_p} \dot{t}_k + \log_2(e) \frac{u_k^n}{\dot{u}_k} \theta^2, \quad k = 1, \dots, K, \\ & \theta \bar{F}(\dot{\mathbf{c}}, \dot{u}_k; \mathbf{c}^n, u_k^n) \geq \rho_d N^2 \sum_{k' \neq k}^K |\bar{\boldsymbol{\gamma}}_{k'k}^T \dot{\mathbf{c}}_{k'}|^2 + \rho_d N \sum_{k'=1}^K \|\mathbf{D}_{k'k} \dot{\mathbf{c}}_{k'}\|_2^2 + \theta^2, \end{cases} \quad (37\text{a})$$

where $\dot{\mathbf{c}}_k \triangleq [\dot{c}_{1k}, \dots, \dot{c}_{Mk}]^T$, $\dot{\mathbf{c}} \triangleq [\dot{\mathbf{c}}_1^T \dots \dot{\mathbf{c}}_K^T]^T$, and

$$\begin{aligned} & \bar{F}(\dot{\boldsymbol{\eta}}, \dot{u}_k; \boldsymbol{\eta}^n, u_k^n) \\ & \triangleq \theta f(\boldsymbol{\eta}^n, u_k^n) + \frac{2\rho_d}{u_k^n} \sum_{k'=1}^K \mathbf{c}_{k'}^{nT} (N^2 \bar{\boldsymbol{\gamma}}_{k'k} \bar{\boldsymbol{\gamma}}_{k'k}^T + N \mathbf{D}_{k'k}^2) (\dot{\mathbf{c}}_{k'} - \theta \mathbf{c}_{k'}^n) - \frac{f(\mathbf{c}^n, u_k^n)}{u_k^n} (\dot{u}_k - \theta u_k^n). \end{aligned} \quad (38)$$

Note that (37g) is a rotated cone and admits a SOC representation. We numerically observe that modern convex solvers such as GUROBI [22] or MOSEK [23] can solve (37) of relatively large size, at least sufficient to characterize the performance of cell-free massive MIMO considered in our paper. The algorithm for solving (28) can be summarized as follows.

Algorithm 1 (Sequential convex approximation algorithm for (28)):

1. *Initialization*: set $n = 1$, choose the initial point of $(\dot{\mathbf{c}}, \dot{\mathbf{u}})$ as $(\dot{\mathbf{c}}^1, \dot{\mathbf{u}}^1)$, where $\dot{\mathbf{u}} \triangleq [\dot{u}_1, \dots, \dot{u}_K]^T$. Choose the spectral efficiency targets $\{S_{ok}\}$, $k = 1, \dots, K$. Define a tolerance ϵ and the maximum number of iterations N_I .²
2. *Iteration n* : solve (37). Let $(\dot{\mathbf{c}}^*, \dot{\mathbf{t}}^*, \dot{\mathbf{u}}^*, \theta^*)$ be the solution.
3. If $\left| \sum_{k=1}^K \left(\dot{t}_k^* - \dot{t}_k^{(n)} \right) \right| < \epsilon$ or $n = N_I \rightarrow$ Stop. Otherwise, go to step 4.
4. Set $n = n + 1$, update $(\dot{\mathbf{c}}^n, \dot{\mathbf{u}}^n) = (\dot{\mathbf{c}}^*, \dot{\mathbf{u}}^*)$, go to step 2.

Remark 1: We recall that for a given spectral efficiency target S_{ok} , the feasible set of (25) is convex, so finding an initial point to start Algorithm 1 can be done easily by solving a feasibility SOCP. If the problem is infeasible, we simply set $E_e = 0$.

Convergence Analysis

The convergence analysis of Algorithm 1 follows standard arguments for the general framework of SCA [17], [18]. Specifically, an optimal solution of $(\hat{\mathcal{P}}_{1,n})$ is also feasible to $(\hat{\mathcal{P}}_{1,n+1})$, due to the use of convex bounds mentioned above. As a result, Algorithm 1 yields a non-decreasing sequence of objectives. We also note that due the total power constraint, the objective of $(\mathcal{P}_1)$ is bounded from above. Thus the objective of Algorithm 1 is guaranteed to converged.

V. ACCESS POINT SELECTIONS

Compared with colocated massive MIMO systems, cell-free massive MIMO systems require more backhaul connections to transfer the data between the APs and the CPU. This is reflected by the last term of (20) (representing the total power consumption of the backhaul) which is proportional to the sum spectral efficiency and the numbers of APs. By dividing the numerator and the denominator of the total energy efficiency (21) by $B \cdot S_e$, we get

$$E_e = \frac{1}{\frac{\bar{P}_{\text{fix}} + \rho_d N_0 N \sum_{m=1}^M \frac{1}{\alpha_m} \sum_{k=1}^K \eta_{mk} \gamma_{mk}}{B \cdot S_e} + \sum_{m=1}^M P_{\text{bt},m}}. \quad (39)$$

We can see that the backhaul power consumption—the second term of the denominator of (39)—affects significantly the energy efficiency, especially when M increases. To improve the total

²It is shown in the numerical results that Algorithm 1 converges quickly after about 10 iterations.

energy efficiency, we can decrease the first term of the denominator of the energy efficiency in (39) or/and reduce the backhaul power consumption. With the proposed power allocation scheme in preceding sections, we just minimize the first term, ignoring the effect of the backhaul power consumption. That is, there is still room to further increase the total energy efficiency of the system.

In this section, we propose two access point selection schemes which can reduce the backhaul power consumption, and hence, increase the energy efficiency. The proposed schemes are based on two main observations:

- The backhaul between the CPU and the m th AP is used to transfer the data $q_1, \dots, q_K$. Thus, the backhaul power consumption depends on the spectral efficiencies $S_{e1}, \dots, S_{eK}$. If the m th AP serves only some users, then it needs to send only the data corresponding to these users. As a result, the backhaul power consumption depends only on the spectral efficiencies of these users. Let $\mathcal{U}_m$ be the set of users served by the m th AP. Then, the backhaul consumption corresponding to the m th AP (19) is now modified as

$$P_{\text{bh},m} = P_{0,m} + B \cdot \sum_{k \in \mathcal{U}_m} P_{\text{bt},m} S_{ek}. \quad (40)$$

Clearly, if $\mathcal{U}_m = \{1, \dots, K\}$ for all m , then (40) is identical to (19).

- For a given user, there are many APs which are located very far away. These APs will not add significantly to the overall spatial diversity gains. This implies that not all APs really participate in serving this user.

Motivated by the above observations, and in order to save the power consumption (and therefore, increase the total energy efficiency), each user should not be served by all APs. Instead, a group of APs should be chosen for each user. In this section, we propose two simple AP selection methods: received-power-based selection and largest-large-scale-fading-based selection.

A. Received-Power-Based Selection

Based on the optimal power control coefficients obtained from Algorithm 1, we can determine how much useful power is transferred from each AP to a given user, and hence, we can select a group of APs which effectively serves that user. With the received-power-based selection scheme, a group of APs are chosen to serve the k th user, denoted by $\mathcal{A}_k$, fulfills the following criteria:

(i) it contributes at least $\delta\%$ of the total received power of the desired signal at the k th user, and (ii) its cardinality is minimum.

From (11), the total received power of the desired signal is represented by DS_k ,

$$\text{DS}_k = \sqrt{\rho_d} N \sum_{m=1}^M \sqrt{\eta_{mk}} \gamma_{mk}, \quad (41)$$

in which the m th AP contributes an amount of $\sqrt{\rho_d} N \sqrt{\eta_{mk}} \gamma_{mk}$. Therefore, the m th AP contributes a fraction

$$p(m, k) = \frac{\sqrt{\eta_{mk}} \gamma_{mk}}{\sum_{m'=1}^M \sqrt{\eta_{m'k}} \gamma_{m'k}} \quad (42)$$

of the total received power at the k th user. As a result, $\mathcal{A}_k$ includes $|\mathcal{A}_k|$ APs that correspond to the $|\mathcal{A}_k|$ largest $p(m, k)$ and $\sum_{m \in \mathcal{A}_k} p(m, k) \geq \delta\%$. To find $\mathcal{A}_k$, we can first order $\{p(m, k)\}$, $m = 1, \dots, M$, in descending order: $p(k^{(1)}, k) \leq p(k^{(2)}, k) \leq \dots \leq p(k^{(M)}, k)$, where $k^{(m)} \in \{1, \dots, M\}$. Then we choose M_k so that $\sum_{m=1}^{M_k} p(k^{(m)}, k) \geq \delta\%$ and $M_{0,k}$ is minimum. The set $\mathcal{A}_k$ is $\{k^{(1)}, \dots, k^{(M_k)}\}$. After choosing K sets $\mathcal{A}_k$, $k = 1, \dots, K$, we can determine $\mathcal{U}_m$ (recall that $\mathcal{U}_m$ is the set of users served by the m th AP).

With our AP selection scheme, the energy efficiency maximization problem in (23) becomes

$$(\mathcal{P}_2) : \begin{cases} \max_{\{\eta_{mk}\}} \frac{B \cdot S_e}{\bar{P}_{\text{fix}} + \rho_d N_0 N \sum_{m=1}^M \frac{1}{\alpha_m} \sum_{k=1}^K \eta_{mk} \gamma_{mk} + B \cdot \sum_{m=1}^M \sum_{k \in \mathcal{U}_m} P_{\text{bt},m} S_{ek}} \\ \text{s.t.} \quad S_{ek} \geq S_{ok} \\ \sum_{k \in \mathcal{U}_m} \eta_{mk} \gamma_{mk} \leq 1/N, \quad m = 1, \dots, M \\ \eta_{mk} \geq 0, \quad k = 1, \dots, K, \quad M = 1, \dots, M, \\ \eta_{mk} = 0, \quad k \notin \mathcal{U}_m, \quad M = 1, \dots, M. \end{cases} \quad (43)$$

Since the power control coefficients $\{\eta_{mk}\}$ are always coupled with γ_{mk} in the objective function as well as the constraints, the optimization problem $(\mathcal{P}_2)$ is equivalent to

$$(\mathcal{P}_2) : \begin{cases} \max_{\{\eta_{mk}\}} \frac{B \cdot S_e}{\bar{P}_{\text{fix}} + \rho_d N_0 N \sum_{m=1}^M \frac{1}{\alpha_m} \sum_{k=1}^K \eta_{mk} \hat{\gamma}_{mk} + B \cdot \sum_{m=1}^M \sum_{k \in \mathcal{U}_m} P_{\text{bt},m} S_{ek}} \\ \text{s.t.} \quad S_{ek} \geq S_{ok} \\ \sum_{k=1}^K \eta_{mk} \hat{\gamma}_{mk} \leq 1/N, \quad m = 1, \dots, M \\ \eta_{mk} \geq 0, \quad k = 1, \dots, K, \quad M = 1, \dots, M, \end{cases} \quad (44)$$

where $\hat{\gamma}_{mk} = \gamma_{mk}$ when $k \in \mathcal{U}_m$ and 0 otherwise.

The denominator of the objective function in (44) involves the discrete sets $\mathcal{U}_m$, $m = 1, \dots, M$. Unfortunately, we cannot solve (44) directly using convex optimization tools. Yet, by using the following bound,

$$\sum_{m=1}^M \sum_{k \in \mathcal{U}_m} P_{\text{bt},m} S_{\text{e}k} \leq \sum_{m=1}^M \sum_{k=1}^K P_{\text{bt},m} S_{\text{e}k} = \sum_{m=1}^M P_{\text{bt},m} S_{\text{e}},$$

we can efficiently find an approximate solution of (44) by replacing $\sum_{m=1}^M \sum_{k \in \mathcal{U}_m} P_{\text{bt},m} S_{\text{e}k}$ with $\sum_{m=1}^M P_{\text{bt},m} S_{\text{e}}$ which is in turn identical to (23), but γ_{mk} is now replaced with $\hat{\gamma}_{mk}$.

The algorithm to implement the received-power-based selection scheme is summarized as follows.

Algorithm 2 (Received-power-based selection):

1. Choose δ , perform Algorithm 1 to find optimal power coefficients $\{\eta_{mk}^*\}$. Then, compute $p(m, k)$ according to (42).
 2. For each k , find set $\mathcal{A}_k$: Sort $p(m, k)$ in descending order $p(k^{(1)}, k) \leq p(k^{(2)}, k) \leq \dots \leq p(k^{(M)}, k)$, where $k^{(m)} \in \{1, \dots, M\}$. Let $\mathcal{A}_k = \{k^{(1)}\}$.
for $i = 2$ **to** M **do**
 if $\sum_{m \in \mathcal{A}_k} p(m, k) \geq \delta\%$ **then** stop,
 else $\mathcal{A}_k = \mathcal{A}_k \cup \{k^{(i)}\}$,
 end if
end for
 3. From $\mathcal{A}_k$, determine $\mathcal{U}_m$, $m = 1, \dots, M$. Let $\hat{\gamma}_{mk} = \gamma_{mk}$ when $k \in \mathcal{U}_m$ and 0 otherwise, $k = 1, \dots, K$, $m = 1, \dots, M$.
 4. Use Algorithm 1, but replace $\gamma_{m,k}$ with $\hat{\gamma}_{mk}$, to find optimal power coefficients $\{\eta_{mk}\}$.
-

B. Largest-Large-Scale-Fading-Based Selection

In the received-power-based selection scheme, the sets $\mathcal{A}_k$, $k = 1, \dots, K$, are chosen based on the power control coefficients $\{\eta_{mk}\}$ obtained from Algorithm 1. It means that we have to perform Algorithm 1 to find $\mathcal{A}_k$ which incurs high computational complexity. In this section, we propose a simpler method, called largest-large-scale-fading-based selection method, which chooses $\mathcal{A}_k$ without the implementation of Algorithm 1.

With the largest-large-scale-fading-based selection method, the k th user is associated with only $M_{0,k} \leq M$ APs corresponding to the $M_{0,k}$ largest large-scale fading coefficients. The main question arising immediately is how to choose $M_{0,k}$. Naturally, we can choose $M_{0,k}$ APs which satisfy

$$\sum_{m=1}^{M_{0,k}} \frac{\bar{\beta}_{mk}}{\sum_{m'=1}^M \beta_{m'k}} \geq \delta\%, \quad (45)$$

where $\{\bar{\beta}_{1k}, \dots, \bar{\beta}_{Mk}\}$ is the sorted (in descending order) set of the set $\{\beta_{1k}, \dots, \beta_{Mk}\}$. After choosing $\mathcal{A}_k$, we can follow the same method as in Section V-A to find optimal power control coefficients.

The algorithm to implement the strongest-large-scale-fading-based selection method is summarized as follows.

Algorithm 3 (Largest-large-scale-fading-based selection):

1. By using (45), user k chooses a group of $M_{0,k}$ serving APs which correspond to the $M_{0,k}$ largest large-scale fading coefficients. Then, we can determine $\mathcal{U}_m, m = 1, \dots, M$.
 2. Let $\hat{\gamma}_{mk} = \gamma_{mk}$ when $k \in \mathcal{U}_m$ and 0 otherwise, $k = 1, \dots, K, m = 1, \dots, M$.
 3. Use Algorithm 1, but replace $\gamma_{m,k}$ with $\hat{\gamma}_{mk}$, to find the optimal power coefficients $\{\eta_{mk}\}$.
-

VI. NUMERICAL RESULTS AND DISCUSSION

In this section, we provide numerical results to quantitatively study the performance of cell-free massive MIMO in terms of its total energy efficiency, as well as to verify the benefit of our AP selection schemes.

A. Parameters and Setup

The APs and the users are located within a square of $D \times D$ km². The square is wrapped around at the edges to avoid boundary effects. Furthermore, for simplicity, random pilot assignment is used. With random pilot assignment, each user randomly chooses a pilot sequence from a predefined set of τ_p orthogonal pilot sequences of length τ_p symbols.

The large-scale fading coefficient β_{mk} is modeled as the product of path loss and shadow fading:

$$\beta_{mk} = \text{PL}_{mk} \cdot z_{mk}, \quad (46)$$

where z_{mk} represents the log-normal shadowing with the standard deviation σ_{sh} , and PL_{mk} represents the three-slope path loss given by (in dB) [24]

$$\text{PL}_{mk} = \begin{cases} -L - 35 \log_{10}(d_{mk}), & \text{if } d_{mk} > d_1 \\ -L - 15 \log_{10}(d_1) - 20 \log_{10}(d_{mk}), & \text{if } d_0 < d_{mk} \leq d_1 \\ -L - 15 \log_{10}(d_1) - 20 \log_{10}(d_0), & \text{if } d_{mk} \leq d_0 \end{cases} \quad (47)$$

where L is a constant depending on the carrier frequency, the user and AP heights. In all examples, we choose $\sigma_{\text{sh}} = 8$ dB, $d_0 = 10$ m, $d_1 = 50$ m, and $L = 140.7$ dB. These parameters resemble those in [6].

Regarding the power consumption parameters, unless otherwise stated, we keep the power consumption parameters as in Table I. These values are taken from [11], [14]. In addition, we choose $B = 20$ MHz, a noise figure equal to 9 dB, $\rho_d = 1$ W, $\rho_p = 0.2$ W, and $\tau_c = 200$.

B. Results and Discussions

1) *Power Allocation*: First, we evaluate the effectiveness of our power allocation in maximizing the total energy efficiency as well as the convergence behavior of Algorithm 1. Figure 1 shows the total energy efficiency obtained via Algorithm 1 versus the number of iterations N_1 , with $N = 1$, $D = 1$ km, $\tau_p = 20$, and different M , K for an arbitrary large-scale fading realization. For small network configurations, we benchmark Algorithm 1 with the optimal solution achieved by a BRB method. To do this, we modify the code for optimal downlink beamforming in [25].

TABLE I
POWER CONSUMPTION PARAMETERS.

Parameter	Value
Power amplifier efficiency, $\alpha_m, \forall m$	0.4
Internal power consumption/antenna, $P_{\text{ic},m}, \forall m$	0.2 W
Fixed power consumption/each backhaul, $P_{0,m}, \forall m$	0.825 W
Traffic-dependent backhaul power consumption, $P_{\text{bt},m}, \forall m$	0.25 W/(Gbits/s)

Fig. 1. The total energy efficiency versus the number of iterations. Here, $N = 1$, and $\tau_p = 20$.

Fig. 2. Average total energy efficiency versus the number of APs, with and without power control. Here, $N = 1$, $D = 1$ km, and $\tau_p = 20$.

Fig. 3. Average total energy efficiency versus the traffic-dependent power, P_{bt} , with and without AP selection schemes. Here, we assume that $P_{bt,m} = P_{bt}$ for all m , $M = 100$, $N = 1$, $K = 40$, $D = 1$ km, and $\tau_p = 40$.

Although, there is no guarantee that SCA-based method can yield an optimal solution in theory, our numerical results show that Algorithm 1 indeed converges to an optimal solution for small size networks in most cases. However, the effectiveness of Algorithm 1 for large-scale networks is still unknown simply because the BRB method fails to work on such large-scale problems. We can also see that Algorithm 1 converges very fast, within about 10 iterations. Therefore, hereafter we choose $N_1 = 10$ for Algorithm 1. Furthermore, we choose $\epsilon = 0.01$.

To further evaluate the effectiveness of the proposed power allocation method, we compare the average energy efficiency of our power allocation and the case without power control (see Figure 2). The average is taken over the large-scale fading realizations. For the case without power control, all APs use full power, and the power control coefficients η_{mk} , $k = 1, \dots, K$, are the same, i.e., $\eta_{mk} = \left(\sum_{k'=1}^K \gamma_{mk'} \right)^{-1}$, $\forall k = 1, \dots, K$. The spectral efficiency target S_{ok} is set to be equal to the spectral efficiency obtained in the case without power control. With power control, the total energy efficiency improves significantly. In particular, compared with the case without power control, the power control can improve the total energy efficiency by factors of more than

Fig. 4. The average number of chosen APs per user. Here, $N = 1$, $K = 40$, and $\tau_p = 40$, $S_{ok} = 1$.

2.9 and 2.6 for the cases of $(M = 100, K = 20)$ and $(M = 100, K = 40)$, respectively. Hereafter, all curves are obtained by using power control. Furthermore, if the problem is infeasible, we set the total energy efficiency equal to 0.

2) *AP Selection*: Next, we examine the performance of our proposed AP selection schemes and the effect of backhaul power consumption on the energy efficiency. Figure 3 shows the average total energy efficiency versus the traffic-dependent power P_{bt} . Here we assume that $P_{bt,m} = P_{bt}$ for all m , and choose $M = 100$, $K = 40$, $N = 1$, $\tau_p = 40$, $D = 1$ km, and the spectral efficiency target is 1 bit/s/Hz, i.e., $S_{ok} = 1$ bit/s/Hz, $k = 1, \dots, K$. For the AP selection schemes, we choose $\delta = 95$ which means the chosen APs contribute at least 95% of the total received power of the desired signal at the each user. Without AP section, the total energy efficiency decreases noticeably as the traffic-dependent power increases. This can be compensated by using our proposed AP selection schemes. Our proposed AP selection schemes work very well and improve the energy efficiency significantly, especially at high $P_{bt,m}$ and large M . Furthermore, it can be seen from the figure that, the received-power-based selection scheme is better than the largest large-scale-fading-based selection one. However, the performance gap is small. Note again that the former scheme has higher computational complexity. The average

Fig. 5. Average total energy efficiency versus the number of antennas per AP. Here, $K = 40$, and $\tau_p = 40$, and $NM = 256$.

numbers of APs chosen by each user are shown in Figure 4. On average, only about 10% – 20% of the total number of APs really participate in serving a given user. These results imply that, it is enough for each user to choose a small number of APs around it, which enables the practical implementation of cell-free massive MIMO. In the remaining numerical results, we consider the received-power-based selection scheme with $\delta = 95$.

3) *Effect of the Number of Antennas per AP:* We examine the performance of cell-free massive MIMO with different numbers of antennas per AP. For fair comparison, the total transmit power in the network is the same, and the number of service antennas is fixed, i.e., $NM = 256$.

Figure 5 shows the average total energy efficiency as a function of the number of antennas per AP. The curves in this figure are generated by using the received-power-based selection scheme (using Algorithm 2). For a fixed total number of service antennas, when the number of antennas per AP increases, the number of APs reduces. The reduction in the number of APs yields a reduction in backhaul power consumption. However, at the same time, the spectral efficiency may decrease since the users are now far away from the APs. This is the reason for why in Figure 5, when N increases, the energy efficiency first increases, approaches the optimal point, and then decreases. The optimal number of AP antennas depends heavily on the system

Fig. 6. Average total energy efficiency versus sum spectral efficiency target. Here, $K = 20$, and $\tau_p = 40$, $D = 1$ km.

parameters, especially the traffic-dependent power $P_{bt,m}$, the spectral efficiency target S_{ok} , and the size of the area. As expected, at high $P_{bt,m}$, low S_{ok} and D , we should use fewer APs with more antennas per AP, and vice versus for low $P_{bt,m}$, high S_{ok} and D .

4) *Cell-Free Massive MIMO v.s Colocated Massive MIMO*: Finally, we compare the energy efficiency of cell-free massive MIMO and colocated massive MIMO. Colocated massive MIMO corresponds to the case $M = 1$. For cell-free massive MIMO, we use the received-power-based selection scheme (Algorithm 2) and the optimal number of antennas per AP (in the sense of maximizing the average energy efficiency). Figure 6 shows the energy efficiency versus the sum spectral efficiency target $\sum_{k=1}^K S_{ok}$. Here, we choose $D = 1$ km and $K = 20$. Compared to the colocated system, cell-free massive MIMO improves system performance significantly. For example, with $S_{ok} = 1$ bit/s/Hz, for all $k = 1, \dots, K$, compared with colocated massive MIMO, the energy efficiency of cell-free massive MIMO improves by factors of about 7.4 and 2.2 for $MN = 128$ and $MN = 256$, respectively. This shows the strong potential of cell-free massive MIMO to boost the energy and spectral efficiency of 5G networks.

VII. CONCLUSION

We investigated the total energy efficiency of a cell-free massive MIMO system with multiple-antenna APs, taking into account the effects of channel estimation, power control (which maximizes the total energy efficiency), non-orthogonality of pilot sequences, and backhaul power consumption. Two AP selection schemes were proposed to reduce the backhaul power consumption. We showed that our power allocation algorithm together with the AP selection schemes can improve the energy efficiency significantly. For a given user, only a small number of APs really participate in serving it. In particular, the cell-free massive MIMO system can provide a very high energy efficiency, while ensuring uniformly good service for all users. With a requirement of 1 bit/s/Hz for each user, cell-free massive MIMO can improve the energy efficiency by an order of magnitude, compared to colocated massive MIMO.

APPENDIX

A. Proof of Proposition 1

From (11), we need to compute DS_k , $\mathbb{E}\{|BU_k|^2\}$, and $\mathbb{E}\{|UI_{kk'}|^2\}$. First, we compute DS_k . Since $\tilde{\mathbf{g}}_{mk}$ and $\hat{\mathbf{g}}_{mk}$ are independent, we have

$$\begin{aligned} \text{DS}_k &= \sqrt{\rho_d} \mathbb{E} \left\{ \sum_{m=1}^M \sqrt{\eta_{mk}} (\hat{\mathbf{g}}_{mk} + \tilde{\mathbf{g}}_{mk})^T \hat{\mathbf{g}}_{mk}^* \right\} \\ &= \sqrt{\rho_d} \sum_{m=1}^M \sqrt{\eta_{mk}} \mathbb{E} \{ \|\hat{\mathbf{g}}_{mk}\|^2 \} \\ &= \sqrt{\rho_d} N \bar{\boldsymbol{\gamma}}_{kk}^T \bar{\boldsymbol{\eta}}_k. \end{aligned} \quad (48)$$

Next, we compute $\mathbb{E}\{|BU_k|^2\}$. From (13), we have

$$\begin{aligned} \mathbb{E}\{|BU_k|^2\} &= \rho_d \mathbb{E} \left\{ \left| \left(\sum_{m=1}^M \sqrt{\eta_{mk}} \mathbf{g}_{mk}^T \hat{\mathbf{g}}_{mk}^* - \mathbb{E} \left\{ \sum_{m=1}^M \sqrt{\eta_{mk}} \mathbf{g}_{mk}^T \hat{\mathbf{g}}_{mk}^* \right\} \right) \right|^2 \right\} \\ &= \rho_d \sum_{m=1}^M \mathbb{E} \left\{ \left| \mathbf{g}_{mk}^T \hat{\mathbf{g}}_{mk}^* - \mathbb{E} \{ \mathbf{g}_{mk}^T \hat{\mathbf{g}}_{mk}^* \} \right|^2 \right\} \\ &= \rho_d \sum_{m=1}^M \eta_{mk} \left(\mathbb{E} \{ |\mathbf{g}_{mk}^T \hat{\mathbf{g}}_{mk}^*|^2 \} - |\mathbb{E} \{ \mathbf{g}_{mk}^T \hat{\mathbf{g}}_{mk}^* \}|^2 \right), \end{aligned} \quad (49)$$

where in (49) we have used $\mathbb{E} \{ (\mathbf{g}_{mk}^T \hat{\mathbf{g}}_{mk}^* - \mathbb{E} \{ \mathbf{g}_{mk}^T \hat{\mathbf{g}}_{mk}^* \}) (\mathbf{g}_{m'k}^T \hat{\mathbf{g}}_{m'k}^* - \mathbb{E} \{ \mathbf{g}_{m'k}^T \hat{\mathbf{g}}_{m'k}^* \})^* \} = 0$, for $m \neq m'$. Using (48) and the identity $\mathbb{E} \{ \|\hat{\mathbf{g}}_{mk}\|^4 \} = N(N+1)\gamma_{mk}^2$, we obtain

$$\begin{aligned}
\mathbb{E} \{ |\text{BU}_k|^2 \} &= \rho_d \sum_{m=1}^M \eta_{mk} \left(\mathbb{E} \{ |\hat{\mathbf{g}}_{mk}^T \hat{\mathbf{g}}_{mk}^* + \|\hat{\mathbf{g}}_{mk}\|^2|^2 \} - \gamma_{mk}^2 \right) \\
&= \rho_d \sum_{m=1}^M \eta_{mk} \left(\mathbb{E} \{ |\hat{\mathbf{g}}_{mk}^T \hat{\mathbf{g}}_{mk}^*|^2 \} + \mathbb{E} \{ \|\hat{\mathbf{g}}_{mk}\|^4 \} - N^2 \gamma_{mk}^2 \right) \\
&= \rho_d \sum_{m=1}^M \eta_{mk} (N \gamma_{mk} (\beta_{mk} - \gamma_{mk}) + N(N+1) \gamma_{mk}^2 - N^2 \gamma_{mk}^2) \\
&= \rho_d N \sum_{m=1}^M \eta_{mk} \gamma_{mk} \beta_{mk}.
\end{aligned} \tag{50}$$

Finally, we compute $\mathbb{E} \{ |\text{UI}_{kk'}|^2 \}$. From (4) and (14), we have

$$\begin{aligned}
&\mathbb{E} \{ |\text{UI}_{kk'}|^2 \} \\
&= \rho_d \mathbb{E} \left\{ \left| \sum_{m=1}^M \sqrt{\eta_{mk'}} b_{mk'} \mathbf{g}_{mk}^T \left(\sqrt{\tau_p \rho_p} \sum_{k''=1}^K \mathbf{g}_{mk''} \boldsymbol{\varphi}_{k''}^H \boldsymbol{\varphi}_{k'} + \tilde{\mathbf{w}}_{p,mk'} \right) \right|^2 \right\} \\
&= \rho_d \mathbb{E} \left\{ \left| \sum_{m=1}^M \sqrt{\eta_{mk'}} b_{mk'} \left(\sqrt{\tau_p \rho_p} \|\mathbf{g}_{mk}\|^2 \boldsymbol{\varphi}_k^H \boldsymbol{\varphi}_{k'} + \sqrt{\tau_p \rho_p} \mathbf{g}_{mk}^T \sum_{k'' \neq k}^K \mathbf{g}_{mk''}^* \boldsymbol{\varphi}_{k''}^T \boldsymbol{\varphi}_{k'}^* + \mathbf{g}_{mk}^T \tilde{\mathbf{w}}_{p,mk'}^* \right) \right|^2 \right\} \\
&= \tau_p \rho_p \rho_d \mathbb{E} \left\{ \left| \sum_{m=1}^M \sqrt{\eta_{mk'}} b_{mk'} \|\mathbf{g}_{mk}\|^2 \boldsymbol{\varphi}_k^H \boldsymbol{\varphi}_{k'} \right|^2 \right\} \\
&+ \tau_p \rho_p \rho_d \mathbb{E} \left\{ \left| \sum_{m=1}^M \sqrt{\eta_{mk'}} b_{mk'} \mathbf{g}_{mk}^T \sum_{k'' \neq k}^K \mathbf{g}_{mk''}^* \boldsymbol{\varphi}_{k''}^T \boldsymbol{\varphi}_{k'}^* \right|^2 \right\} + \rho_d \mathbb{E} \left\{ \left| \sum_{m=1}^M \sqrt{\eta_{mk'}} b_{mk'} \mathbf{g}_{mk}^T \tilde{\mathbf{w}}_{p,mk'}^* \right|^2 \right\},
\end{aligned} \tag{51}$$

where

$$b_{mk} \triangleq \frac{\sqrt{\tau_p \rho_p} \beta_{mk}}{\tau_p \rho_p \sum_{k'=1}^K \beta_{mk'} |\boldsymbol{\varphi}_{k'}^H \boldsymbol{\varphi}_k|^2 + 1}. \tag{52}$$

Since the elements inside the norm of the second and third terms in (51) are uncorrelated, zero

mean RVs, we can rewrite (51) as

$$\begin{aligned}
\mathbb{E} \{ |\mathbf{UI}_{k'}|^2 \} &= \tau_p \rho_p \rho_d \mathbb{E} \left\{ \left| \sum_{m=1}^M \sqrt{\eta_{mk'}} b_{mk'} \|\mathbf{g}_{mk}\|^2 \right|^2 \right\} |\boldsymbol{\varphi}_k^H \boldsymbol{\varphi}_{k'}|^2 \\
&+ \tau_p \rho_p \rho_d \sum_{m=1}^M \sum_{k'' \neq k}^K \eta_{mk'} b_{mk'}^2 \mathbb{E} \left\{ |\mathbf{g}_{mk}^T \mathbf{g}_{mk''}^*|^2 \right\} |\boldsymbol{\varphi}_{k''}^T \boldsymbol{\varphi}_{k'}^*|^2 + \rho_d \sum_{m=1}^M \eta_{mk'} b_{mk'}^2 \mathbb{E} \left\{ |\mathbf{g}_{mk}^T \tilde{\mathbf{w}}_{p,mk'}^*|^2 \right\} \\
&= \tau_p \rho_p \rho_d \mathbb{E} \left\{ \left| \sum_{m=1}^M \sqrt{\eta_{mk'}} b_{mk'} \|\mathbf{g}_{mk}\|^2 \right|^2 \right\} |\boldsymbol{\varphi}_k^H \boldsymbol{\varphi}_{k'}|^2 \\
&+ \tau_p \rho_p \rho_d N \sum_{m=1}^M \sum_{k'' \neq k}^K \eta_{mk'} b_{mk'}^2 \beta_{mk} \beta_{mk''} |\boldsymbol{\varphi}_{k''}^T \boldsymbol{\varphi}_{k'}^*|^2 + \rho_d N \sum_{m=1}^M \eta_{mk'} b_{mk'}^2 \beta_{mk}. \tag{53}
\end{aligned}$$

The expectation that appears in (53) is computed as follows,

$$\begin{aligned}
\mathbb{E} \left\{ \left| \sum_{m=1}^M \sqrt{\eta_{mk'}} b_{mk'} \|\mathbf{g}_{mk}\|^2 \right|^2 \right\} &= \mathbb{E} \left\{ \sum_{m=1}^M \eta_{mk'} b_{mk'}^2 \|\mathbf{g}_{mk}\|^4 \right\} \\
&+ \mathbb{E} \left\{ \sum_{m=1}^M \sum_{n \neq m}^M \sqrt{\eta_{mk'} \eta_{nk'}} b_{mk'} b_{nk'} \|\mathbf{g}_{mk}\|^2 \|\mathbf{g}_{nk}\|^2 \right\} \\
&= N(N+1) \sum_{m=1}^M \eta_{mk'} b_{mk'}^2 \beta_{mk}^2 + N^2 \sum_{m=1}^M \sum_{n \neq m}^M \sqrt{\eta_{mk'} \eta_{nk'}} b_{mk'} b_{nk'} \beta_{mk} \beta_{nk}. \tag{54}
\end{aligned}$$

Inserting (54) into (51), and using (52), we obtain

$$\mathbb{E} \{ |\mathbf{UI}_{kk'}|^2 \} = \rho_d |\boldsymbol{\varphi}_k^H \boldsymbol{\varphi}_{k'}|^2 N^2 \left(\sum_{m=1}^M \sqrt{\eta_{mk'}} \gamma_{mk'} \frac{\beta_{mk}}{\beta_{mk'}} \right)^2 + \rho_d N \sum_{m=1}^M \eta_{mk'} \gamma_{mk'} \beta_{mk}. \tag{55}$$

The substitution of (48), (50), and (55) into (11) yields (15).
